

SAFETY, REPORTING & PROTECTION

Vimbiso

A WhatsApp-first risk-triage tool that responds to a survivor the moment she reports — no waiting, no second report required.

OSF / Andela Hackathon · Kenya Pilot · Built solo by Nnouka

A documented crisis — and a live transparency failure

220

femicides documented
in Kenya in 2025

129

in Q1 2025 alone —
roughly one a day

1,069

women killed,
2016–2025

The Kenyan government stopped publishing femicide data after March 2025.

That's not just a severity statistic — it's a live, current trust and transparency failure. A survivor today has less official visibility into this crisis than a survivor had a year ago.

The mechanism most pitches get wrong

Our first design

- A "matching-escrow" model: a survivor's report only became visible once a second, independent report named the same perpetrator.
- Modeled on real evidence from Cameroon's femicide pattern — but real cases show a first report can be the last chance to help someone.
- Waiting for corroboration before responding is a fatal design flaw for a HIGH-risk case.

What we corrected it to

- Risk-triage first: every report runs through an 8-question screen based on documented lethality-risk factors.
- A single HIGH-risk report triggers an immediate, automatic safety response — no second person, no waiting.
- Pattern-matching across reports still exists — demoted to a non-urgent, consent-gated "Pattern Watch" feature, never the primary safety path.

One report. One response. No waiting.

Verified live: a real WhatsApp message through the Twilio Sandbox — backend and dashboard both deployed on Render, Postgres on Supabase — ran the full sequence end-to-end: safety plan, a real SMS confirmed in the Twilio console reaching the on-call counsellor, and the report showing correctly on the live dashboard.

Trust is the whole track — so privacy isn't a feature, it's the architecture

No legal-name field, anywhere

reports and trusted_contacts have no name/legal_name/id_number column — confirmed by direct schema inspection, not just design intent.

A perpetrator is hashed, never named

HMAC-SHA256, salted — a live audit searched every text column in every table and found zero raw text outside the intended hash.

Every cross-report action is consent-gated

perpetrator_consent_given and wants_counsellor_connect default false — verified: no hash row, no SMS, unless the survivor explicitly said yes.

Anonymous by default, reversible only by lawful process

Message-analysis logging pseudonymizes senders with a one-way hash no key can reverse — a separate, custodian-held key (never in normal app config) allows lawful re-identification via a standalone script, and every use is audit-logged. Built and verified end-to-end against a real database.

Language coverage — stated exactly as built, not as planned

Language	Tier	Keys	What's actually covered
English	FULL	87	Every user-facing string in the product.
Swahili	PARTIAL, unreviewed	11	Only the safety-critical HR-1 sequence + Pattern Watch consent. Everything else falls back to English.
French	PARTIAL, unreviewed	11	Same safety-critical subset. Nnouka (native speaker, core team) has committed to reviewing it.
Arabic / Kinyarwanda	Architecture-only	0	Schema supports adding these instantly — no content drafted yet; contingent on volunteer reviewers.

A language never claims more completeness than it has: content_strings carries its own tier column, and the code logs — and falls back to English — the instant a key is missing.

What's real, and what's honestly still simulated

Real

- Full conversation state machine, risk scoring, and hashing — real code
- Live end-to-end test: a real WhatsApp message through the Twilio Sandbox, on Render (backend + dashboard) with Postgres on Supabase, ran the full HIGH-risk flow
- A real SMS reached the on-call counsellor, confirmed in the Twilio console — and the report appeared correctly on the live, Supabase-backed dashboard

Still simulated

- The on-call counsellor is a single demo Twilio number, not a live HAK/1195 integration
- No masked-relay number — a survivor's real WhatsApp number is the identifier used
- Swahili and French remain PARTIAL tier, AI-drafted, and unreviewed

Why Kenya — a real comparison, not a default

1

Strongest, most current data

Kenya's crisis data is the most multi-sourced of the countries compared (Zimbabwe, Cameroon, Rwanda, Tanzania) — and the government's own publishing gap makes the transparency case immediate.

2

A real institution to hand off to

HAK/1195 is a dedicated, UN-backed, actively-promoted national toll-free GBV helpline — makes "connect me to a counsellor" credible, not aspirational.

3

An actual hackathon community

Kenya (@KEN) is a real participating Andela chapter, alongside Cameroon (@CMR) and Rwanda (@RWA) — a concrete channel for translation reviewers, not cold outreach.

Honestly weighed against: Cameroon's data was the reason risk-triage became our core mechanism — but weak routing infrastructure there means Vimbisio, a “smart front door,” has no reliable door to stand in front of yet.

One human founder — AI agents disclosed honestly

Tendai Moyo

An AI agent persona from ideation — not a real person.

One of four AI agent personas used for competitive ideation (see AI Tool Usage Log). Generated the original concept, then pressure-tested it against real evidence.

Nnouka

Cameroonian, based at CMU Africa in Kigali, working with Andela. Fluent English / French / Pidgin.

Sole human founder and builder. Leads the French-language build and review as a native speaker and core team member — the same market whose femicide data corrected our core safety mechanism during development. Also coordinating a Kinyarwanda lead through Kigali networks.

Phase 2 roadmap

Real HAK/1195 handoff

Move past a demo on-call number to an actual integration agreement, so counsellor-connect is a real warm handoff, not a simulated one.

Real translation review

Swahili and French moved from PARTIAL/unreviewed to FULL/reviewed via @KEN and Nnouka's own review.

Cameroon & Rwanda expansion

Once real institutional GBV-response partnerships exist to hand survivors off to — not before.

USSD / low-bandwidth channel

Serves the ~60% of Kenyans not yet online — reframed as inclusion, not the pitch's central differentiator.

A single report is enough.

Vimbiso responds the moment someone reaches out — with a real safety plan, a real hotline, and a real path to a counsellor. Built honestly: every claim in this deck is backed by real code, a real database, and a documented source.
